Executive summary

This report examines the life-cycle costs of using various appliance-fuel combinations in low-income households in urban South Africa. For cooking, water heating, space heating, lighting and refrigeration services, the life cycle costs faced by end-users are calculated. The present values of these are amortised to common bases, such as 10 useful Megajoules of energy for the thermal services (cooking, water and space heating), 1000 lumen-hours for lighting and Rands per day (for refrigeration). The estimates are ranked from lowest to highest cost. In estimating the life-cycle costs, some assumptions are made, and these, along with empirical price variations, are utilised in testing the sensitivity of the LCC to input variables.

It is clear that the ranges of LCCs are broad, and in some instances extend to three times or more of the minimum of the range. In most instances the estimated range of LCCs does not provide incisive clarity as to which appliance/fuel combination will deliver the lowest priced energy service to the end-user. However, this reflects the reality of appliance and fuel combinations in use. Because the cost depends on a large number of parameters, not least, the behaviour of the end-user, there is much uncertainty as to which combinations will provide the least-cost service. Thus the compounding effect of many small variations in the parameters can result in large LCC variations.

The conclusion that too much variation exists to make direct comparisons is fortunately not the rule. To simplify analysis, the mid-point of price ranges was used. On this basis, some appliance-fuel combinations provide services distinctly cheaper than others. Lighting and refrigeration are services where grid electricity will provide services at considerably lower cost than with all other competitive commercial fuel and appliance combinations. Similarly, a clear conclusion can be drawn from the range of LCCs describing water heaters, where integral solar water heaters have significantly lower LCCs than all others. But despite the low LCC at which the integral solar water heater provides the water heating service, the quality of the service cannot be realistically compared with the provision of hot water on demand. A second best could be either a solid fuel stove with a water jacket or a solar/electric water heater, which uses electricity to top up the solar shortfall and provide hot water on demand.

The comparisons of levels of service with respect to water heating is one methodological question that needs to be considered when policy is developed, but a similar questions can be raised about the LCC methodology when applied to lighting. Will, for example, end-users be making choices on the basis of lumens when choosing lighting, or will any light source be adequate regardless of its quality? If the latter is closer to the end-users' reality, then a candle may provide a lower cost lighting source than the electric lamp. Such observations may provide some insight into the slower than anticipated movement towards electrical saturation of low-income household energy services.

Amongst the thermal energy services, uncertainty about the lowest priced option is greater since LCCs are confined within a comparatively narrow range compared, to say, the lighting LCCs. It is apparent that unless solid fuels are available, cheap and clean, the possibility to meet energy service needs could feasibly be any one of the electrical, gas or paraffin options. Though what has not been factored in are the externalities that can affect health negatively through burns, indoor and outdoor pollution, fires.

The main conclusions which can be drawn from the financial cost analysis are the following. The least-cost financial cost options for fulfilling the energy services are:

- coal stoves for cooking;
- heat-pumps (for multi-family dwellings and commercial buildings) and coal stoves for space heating;
- integral solar water heaters for water heating;
- 18W compact fluorescents for lighting; and
- electric fridges and freezers for refrigeration.

The outcome of this life-cycle costing exercise should ideally be used to develop a least-cost mix of options from a national economic perspective.

The sensitivity of the national average LCCs for cooking fuels and appliances are tested by varying fuel price, appliance price, energy efficiency, durability and real discount rates independently. As fuel price, appliance price, and discount rates increase, so do the LCCs. When energy efficiency and durability increase, the trend is one of decreasing LCCs. The sensitivity is linked to the proportional contributions to the total LCC of the operational and appliance price components and the breadth of the ranges being tested. For example, gas rings for cooking have a LCC which is almost entirely made up of operational costs. So there is little sensitivity to appliance price, appliance durability and the discount rate, but high sensitivity to energy efficiency and fuel price.

1

Introduction

The work contained in this report constitutes part of the research programme entitled '*Energy efficiency, equity and environment: improving access to energy services for the urban poor of South Africa*'. The paper aims to provide a robust assessment of the cost implications for households of various appliance-fuel combinations in meeting basic energy needs in low-income urban South Africa in 1996. This report is one of several being produced in this phase of the project, and follows several reports published earlier (Thorne 1996, Simmonds 1996, Mammon 1996).

This report provides estimates of the financial life-cycle costs of different fuel and appliance combinations and ranks them from lowest to highest cost. This is a necessary step for purposes of developing a least cost energy plan. Based on the savings potential that will accrue to end-users, the national economy and other stakeholders, a selection of urban demand-side management (DSM) options can be selected and costed and policy instruments designed to achieve lower cost energy services.

The main output of the paper is the presentation of life-cycle cost estimates and sensitivity analyses. Before listing these, the methodologies used in their estimation are discussed in Chapter 2, which also identifies data sources. Chapter 3 summarises the estimated costs of fulfilling basic energy services, estimating the life-cycle cost (or financial cost) of the fuel and appliance combinations. Sensitivity to assumptions and variables are tested in Chapter 4. The final chapter, Chapter 5, draws some conclusions, without pre-empting future phases in the project which will identify the costs and benefits of selected least-cost energy services and strategies to approach them.

The paper has been kept as readable as possible; the large amounts of data and calculations involved in estimating the costs are presented as figures and tables in the body of the text, and the details supporting the results can be found in the appendices.

2

Methodological approach to estimating the financial costs of energy services in urban South Africa

2.1 Introduction

An important policy goal for government is to determine the economic least-cost mix of energy services and to design appropriate policy instruments to achieve this mix. In support of this goal, this paper sets out to evaluate the financial costs to end-users under the status quo. This chapter briefly discusses the life-cycle assessment and costing methodologies and sources of data. The specific methodological steps taken and detailed calculations of estimating the cost of energy services are included in Appendices A to F; the questionnaires and the raw data acquired during the appliance cost surveys are in Appendices G and H.

Calculations of costs are based on available prices and costs, such as appliance life-spans, energy transformation efficiencies, average power output of, for example, stoves and heaters during their operational lives, and so on. As there are gaps in current data on energy services, particularly appliance costs, the project included a short primary data collection phase.

2.2 Methodologies

In introducing the selected methodologies utilised in this paper, it is necessary to discuss some of the more popular methodologies applied to the estimation of costs associated with the supply and/or use of fuels and appliances. These methodologies, although initially applied to the energy supply industry, are not exclusively confined to energy applications, but have generic applications to products and processes, and are used increasingly as management and accounting tools in industrialised countries.

The life-cycle assessment (LCA) and the life-cycle cost (LCC) estimate are the central focus. Other life-cycle tools are: life-cycle accounting, analysis, design, inventories, management, and review (LCA Source Book 1993: 112).

Product life-cycles can be organised into the following stages:

- raw material acquisition;
- bulk material processing;
- engineering and speciality materials production;
- manufacturing and assembly;
- use and service;
- retirement; and
- disposal (EPA 1993: 13).

The present study is primarily directed to the product use and service stage.

2.2.1 Life-cycle assessment

Life-cycle thinking and techniques can be applied to products, processes or systems in various ways. The most all-encompassing approach used in evaluating the implications of the products and processes is life-cycle assessment. This is the overall process of assessing the life-cycle impacts associated with a system, function, product or service (LCA Source Book 1993: 111). Described in another way, LCA is one of the tools used to examine the economic and environmental cradle-to-grave consequences of making and using products or providing services (SETAC 1993).

The LCA comprises a range of techniques promoted on the basis that they can help to assess a product's life-cycle economic costs (abbreviated to LCA_{econ}), social costs (LCA_{soc}) or environmental costs (LCA_{env}). Such analysis is often referred to as looking at the 'cradle-to-grave' impacts of products or systems (LCA Source Book 1993: 15).

The LCC estimate must be contrasted with the LCA and a life-cycle cost inventory (LCI). There are numerous tools that can be applied to the assessment of life-cycle costs and numerous perspectives from which they can be applied. For example, the suppliers' perspective could be explained as follows:

[A] company may investigate the life-cycle cost of its products, for example, hoping to cut them - or to prove to customers that the high initial purchase cost will be offset by lower overall life-cycle costs. (LCA Source Book 1993: 15)

LCA typically includes four phases: initiation, inventory, impact assessment and improvement. These phases are called the four 'Is' of LCA, which are expanded as follows:

1. the initiation phase – scoping a process to define the problem and establish the LCI and LCA objectives;
2. the inventory phase – which provides a detailed picture of the raw material, energy (and water) inputs, used by the system - and of the solid, liquid and gaseous wastes produced as outputs;
3. the impact assessment phase – linking inventoried inputs and outputs to real world environmental problems); and
4. the improvement phase – focusing on changes to the system to improve its overall environmental performance.

It is in the inventory stage where the system boundary is considered. In this respect (as well as in others) the LCA differs from the LCC estimate, which is used in this paper. The LCC is exclusively interested in the end-users' perspective, whose system boundary differs from that of the product or service supplier. The LCC could therefore be considered as a component of LCA.

2.2.2 End-user perspectives on life-cycle costs

An essential part of the end-use oriented approach is the use of economic analysis techniques that allow for a rational comparison among supply, end-use efficiency, and energy alternatives. In the present conventional approach, supply expansion, energy efficiency, improvement and renewable alternatives are planned and implemented by different government agencies using varied and inconsistent economic criteria. The budgets for these activities are determined independently, largely according to fashion or for political reasons. This, together with energy subsidies, market imperfections, and institutional obstacles, leads to gross misallocation of resources. (Asian Development Bank 1994: 196)

The initial step in estimating the costs of appliance-fuel combinations is to select the most appropriate method to estimate the cost to end-users. The method must also provide cost estimates that will facilitate comparisons between different fuel and appliance combinations.

A simple approach to comparing the effectiveness of an appliance and fuel combination is the simple payback period (SPP):

$$\text{SPP} = \text{cost of conservation measure} / \{(\text{annual energy savings}) * (\text{unit price of energy})\}$$

The investment is considered cost effective if the SPP is small – smaller, say, than three to four years.

This indicator has many drawbacks in that:

- it does not take account of the time value of money;
- it does not consider the useful life of the conservation measure;
- it does not compare the conservation measure with alternative investment opportunities open to the end-user;
- it omits the environmental costs of energy provision;
- it masks the tax and subsidy influences on the price of energy; and
- it cannot be used for direct investment comparisons even for end-users, as the lower SPP does not necessarily imply the better investment (Asian Development Bank 1994: 196).

Alternative assessments of cost include the Internal Rate of Return (IRR), Cost of Saved Energy (CSE) (also referred to as the Cost of Conserved Energy (CCE) (Gadgil & Januzzi 1992), Net Present Value (NPV), Life-Cycle Cost (LCC), and Annualised/Amortised Life-cycle Cost (ALC). The SPP, IRR and CSE (CCE) can only be used to make comparisons between two or more alternatives.¹ The ALC provides a common time base for comparison (something that the LCC does not). The ALC, while providing a measure by which a number of options providing identical classes of services can be compared, cannot be used to compare different energy services, like lighting and refrigeration.

The financial analyses have limitations which include foreign exchange implications, the cost of institutional changes, the cost of environmental and/or social impacts, employment consequences and the quality or convenience of the different energy services (Asian Development Bank 1994: 196-202).

In conclusion, the ALC indicator is used to measure and rank the comparative prices of the differing fuel and appliance combinations. In this paper the basis is not time, but rather the price per unit of the energy service (the exception here being the case of refrigeration). These comparative life-cycle costs per unit of service are referred to as LCCs. The step-by-step calculation is included in Appendix A.

2.2.3 The life-cycle cost estimate

The aim of the life-cycle costing exercise in this report is to estimate the cost of fulfilling energy services within the household in different urban centres in South Africa. The cost estimates are based on secondary and primary data, the former compiled by Simmonds and Mammon (1996) on a city-by-city basis, and the latter gathered as part of this study. The paper ranks the costs of the services in order to reveal where the largest savings can be affected.

The costs which are included in the LCC estimate are financial prices (purchase prices, costs of capital, etc.) of appliances and fuels. These prices include taxes, subsidies, and other transfers within the economy, but exclude social costs or costs to the environment (CO₂, NO_x, SO_x, and other emissions), health related costs (morbidity and mortality, poisonings and burns), fires, explosions, and so on. In an economic analysis, on the other hand, taxes and other transfers would be excluded, whilst social and environmental externalities would be included in the assessments.

Fuels/energy sources under consideration in this study are electricity, petroleum fuels (paraffin, liquefied petroleum gas (LPG) and candles), coal, wood, and solar. Appliances for cooking, water- and space-heating, lighting and refrigeration are likewise costed. Where this data could not be sourced for the South African context, comparable figures from elsewhere are utilised for approximations - the energy consumption of refrigerators on the South African market is just such a data gap, although projects are currently being undertaken which assess the energy performance of locally available refrigerators, freezers and combinations of these.

The end-users' costs are those experienced by end-users, as distinct from suppliers or the economy as a whole. They see only the direct financial costs of energy services; however, some of the costs which cover immediate externalities could be considered to be indirectly captured through taxes levied outside of the energy service arena. For example, income taxes are one way in which costs related to health problems amongst household members breathing polluted air can be captured. At the very least, the costs experienced by the user will include the price paid for the appliance and fuel. The life-cycle cost varies as:

- prices paid by consumers for fuels vary from one part of South Africa to another;
- efficiencies of the fuel and appliance combinations vary;
- there are ranges of retail cash and hire purchase prices paid for appliances; and
- the time that each appliance is in use each day differs from household to household.

The maxima and minima of each of these parameters are included in estimating the range within which the LCC is most likely to fall. Assumptions included in calculations are:

¹ It is likely that some of these measures may be used in the next phase of work, where comparisons are required to inform policy.

- the durability of the appliance (in operative hours);
- an average power estimate (units of fuel per operative hour);
- a real discount rate (the rate may change if fuel switching is suggested in strategies). Rate changes are as a result of risks associated with the switch (Hasset & Metcalf 1993; Awerbuch & Deeham 1995);
- the distribution of the cost of gaining access to an energy service (such as the cost of an electricity connection);
- the division of the costs of electrical connections and solid fuel stoves between the different energy services – for example, 15-25% of the cost of the coal stove is attributed to space-heating; and
- the maintenance costs of appliances (these are assumed to be between 10 and 20% of the initial price of the appliance).

For the sake of simplicity, the mid-points of these variables are utilised in estimations of LCCs. The LCC's sensitivity to assumptions and variables that exhibit ranges is tested and reflected in Chapter 4. All costs are in 1996 Rands; where figures from previous years had to be used, these were brought forward to the 1996 baseline using consumer price indices for the intervening years.

2.3 Sources of data

The information required to produce LCC estimates includes: the retail price of fuels and appliances, the cost of finance, efficiency/efficacy of appliances, hours each year the appliance is in use, durability and maintenance requirements. With the exception of operational hours per year, durability and maintenance costs, these figures were obtained either through primary research undertaken as part of this study or from secondary data sources. Where gaps exist, assumptions are made.

A short primary research phase aimed at identifying the current price of the most popular appliances and the cost of purchasing these on hire purchase terms was undertaken (the questionnaire used, and the raw data are included in Appendices G and H respectively).

Sources of price data include the DMEA database. Appliance information is sourced from suppliers, manufacturers and the South African Bureau of Standards. As a last resort the recommended retail price and the product specifications are used as a basis for estimates. Specifications and test data are likely to belie the performance of appliances in situ, and as such remain a last resort. The cost of fuels is sourced from the parallel work of Simmonds and Mammon (1996) which synthesises much secondary data – notably on fuel consumption and prices in Johannesburg, Durban, Port Elizabeth and Cape Town.

3

Life-cycle costs of appliance-fuel combinations

3.1 Introduction

This chapter summarises the life-cycle costs of appliance and fuel combinations commonly used to fulfil domestic energy services in low-income urban South African homes. The services considered include cooking, water-heating and space-heating, lighting and refrigeration. The areas considered are the Johannesburg, Port Elizabeth, Durban and Cape Town metropolitan areas, the data is also aggregated to provide a national average for comparative purposes. The data are, where possible, presented in a graphic form in the text, with more detail on the steps taken in the estimation of the LCCs given in Appendices B to F. The LCCs are based on:

- prices of appliances;
- prices of fuels;
- hire-purchase charges (where relevant);
- discount rates;
- escalation in the prices;
- efficiencies of transformation of the fuel/energy source in the appliance; and
- fuel use per unit of operational time.

The sources of data include both secondary and primary research, technical specifications and best approximations. The fuel costs are taken from reports compiled within the last two to three years. These reports, by and large, each focus on a specific urban area in South Africa. In some instances, the prices were brought forward to 1996 values using appropriate price indices (Simmonds & Mammon 1996). The appliance data were gathered in Cape Town in a process designed specifically to inform this project (the questionnaire used for this process is included as Appendix G). The range of appliance costs include the price paid under hire-purchase agreements.² Conversion efficiency information is drawn from literature surveys. Finally, details of the fuels used per operational unit of time are informed by appliance specifications and secondary data.

3.2 Fuel prices

The fuels used in the life-cycle estimates are priced in the various urban centres. These prices are listed below and include value added tax.

² Hire-purchase agreements are most commonly concluded over a 12-21 month period at a rate between 28 and 31%. The lowest cost of appliances is the cash price; in contrast the highest price includes a 31% interest rate and payment over a 21 month period.

Fuel type	Price by area (* indicates that no data was available)											
	Johannesburg ¹			Port Elizabeth ²			Durban ³			Cape Town ⁴		
	min	mid	max	min	mid	max	min	mid	max	min	mid	max
Electricity (c/kWh)	19.49	23	26.84	20.05	23	26.84	24.17	25.5	26.84	22.86	25	26.84
Connection costs (include deposits)	550	300	50	85	68	50	142.5	96.3	50	350.48	200.2	50
Loose candles (c)	50			*			48	50	54	35	50	65

Notes

1. These are draft figures for a study being completed by the Palmer Development Group. Information is for an area about 160 km north-east of Pretoria.
2. Electricity, coal, paraffin and LPG prices are taken from SA Energy Statistics (1996).
3. Electricity prices are taken from SA Energy Statistics (1996) and other fuel prices are taken from Hoets and Golding (1992) and updated to 1995 levels using the CPI.
4. Paraffin, LPG, vehicle battery, dry battery and candle prices are taken from Mehlwana and Qase (1996). The electricity price is taken from SA Energy Statistics (1996). Coal and wood prices are taken from Cape Coal (Pty) Ltd (1996). The price ranges for coal and wood are based on collected versus delivered prices. Coal is sold in 40 kg bags for between R20.00 and R22.00, while wood is sold in 20 kg bags for between R8.50 and R9.00.

TABLE 3.1 Fuel prices in various urban centres of South Africa

Source: Simmonds and Mammon (1996)

These prices include 14% VAT but, in the case of gas, do not include the price of the larger LPG bottles as, technically, these remain assets of gas companies (the price of servicing the bottles is included in the price of gas) (SAPIA 1996). Similarly, the costs of electrical infrastructure and services which are not paid for in the price per unit are included in estimates. LPG bottles cost the following:

Gas bottles' numbers	Quantity of LPG (kg)	Quantity of energy (watt-hours)	Lowest price (excl. vat)	Highest price (excl. vat)
3	1.4	90	123	125.4
7	3.4	111	136.8	151.6
10	4.5	123	167.6	193.8
13	9	246	228*	228
larger			85.5 (deposit)	-

* Only one source of data was obtained for the no. 13 bottle price and the larger bottle deposits.

TABLE 3.2 The maximum and minimum price of LPG bottles

3.3 Assumptions in estimating life-cycle costs

The LCC estimates can, and should, be provided as a range. Such a depiction is most realistic, as there are many influences on efficiency of energy transformation, prices of fuels and appliances, size and quality of pots etc., which are the reality of meeting energy service requirements. The prices of fuels which are unregulated (such as LPG, wood and coal) can vary from distributor to distributor. For example, LPG in Cape Town is recorded as being priced between R1.66 and R3.66 per kg. Likewise the price of wood can vary considerably from that collected at no financial cost to the end-user, to bundles purchased at a café or garage. Because of the dual economies of wood, it has been suggested that wood stoves and open fires be excluded from the comparison with other fuels in this paper.

To illustrate the ranges of LCCs, Figure 3.1 shows the LCC range for cooking appliance and fuel combinations used in Cape Town.

FIGURE 3.1 The range of LCCs for cooking fuel and appliances in Cape Town

Figure 3.1 while demonstrating the LCC realities provides little information for comparative purposes. To sharpen the estimates of costs for comparative purposes, the methodology employed utilises an arithmetic mid-point in the price ranges and efficiency for the calculation of the metropolitan areas and the national average. The ranges are reflected in the sensitivity analyses included in Chapter 4.

Assumptions and parameters which contribute to the range of prices for fuels and appliances are listed and discussed below.

1 Discount rates and price escalation

A constant real discount rate of 10% has been used. No price escalation have been assumed, so that the real prices of all appliances and fuels have remained constant relative to each other.

Similarly there is a zero increase in the escalation of operation and maintenance of appliances included in the LCCs.

2 Prices

Where required, prices are brought to a common 1996 base using the overall consumer price index. The CPI applies to all items purchased by low-income households, and is as follows: 1993: 8.6%; 1994: 8.7%; and 1995: 8.78% (Central Statistical Services 1995).

3 Maintenance

Similarly, there are insufficient empirical data on maintenance costs. Where such data are not available in the literature, an estimate of between 10% and 20% of the initial purchase price of the appliance is used to reflect these costs.

4 Replacements of parts of appliances

The costs of replacing all or part of an appliance or the infrastructure connecting the household to the electrical network should be incorporated in the LCCs. For simplicity, appliance replacements costs are considered to be part of the maintenance costs, whereas the present value of the replacements of the electrical connection are added to the LCCs separately. In cases where significant replacement costs are planned for such things as bladders for integral solar water heaters, batteries for photovoltaic systems, fluorescent bulbs (without the ballasts), these are factored in over and above the maintenance value through a replacement component in the LCCs.

The replacement costs of electrical reticulation are estimated over a 30-year lifespan.

5 Power factors

To complete a life-cycle cost estimate, a further assumption is needed – the average amount of energy consumed per hour of operation. To overcome the dearth of empirical data, 'power factors' were assumed for each appliance/fuel combination, where they could not be drawn from *Electrowise* (n.d.) data and other sources.

6 Hire-purchase

Hire-purchase costs are added to the high end of the appliance price range. The highest recorded increment is based on finance charges at 31% over a 21 month repayment period. This would typically result in an additional 47% increase to the price of the appliance. While the increment should be added on a monthly basis over the first 21 months after purchase, the cost estimate calculation instead adds 47% to the high end of the appliance price range (for larger appliances which are likely to be purchased on terms) to reflect the cost of financing the hire-purchase in addition to purchase price.

7 Connection cost and multi-utility appliances

In considering the connection and service costs of electricity, a question arises as to how this cost should be divided amongst the different energy services for which electricity could be used. A similar question arises when considering multi-utility appliances such as solid fuel stoves. This could be addressed by using one of the following methods:

- apportioning costs to the services in a ratio accorded to the proportion of electrical energy used;
- apportioning costs (in the case of electricity connection costs) in a ratio accorded to the power demanded by the different energy services; and
- using the 'power factor' and 'hours per day' ranges for each of the appliance/fuel combinations to calculate electrical energy consumption proportions.

Through the reconstruction of energy use utilising end-use survey data (Simmonds & Mammon 1996), the consumption and demand for the different fuels can be estimated. For electricity connection costs, the demand estimates are utilised (as the sizing of the infrastructure is designed with reference to after diversity maximum demand). For solid fuel stoves, the energy consumption for the different services are used to disaggregate the costs between end-uses.

The disaggregation of these costs has been estimated in accordance with delivered energy consumption ranges and is as follows:

<i>Energy service</i>	<i>Electrification</i>	<i>Coal/wood stoves</i>
Cooking	25 to 30	20 to 40
Space-heating	15 to 20	20 to 40
Water-heating (for solar/elec. heaters)	35 to 45 (0.15 to 0.25)	30 to 50
Lighting	5 to 10	-
Refrigeration	5 to 10	-

TABLE 3.3 The percentage division of multiple utilities to different energy services*Source: estimates drawn from Simmonds and Mammon (1996)*

8 Space heating seasons

In the calculations of the space-heating LCCs it is necessary to provide a space-heating season. For the sake of the calculations these are estimated for the 'min', 'mid' and 'max' scenarios to be 2, 3 and 4 months for Durban, and 4, 5 and 6 for the remaining three cities.

9 Other costs

As the LCC estimates are undertaken from an end-use perspective, all costs reflected in the calculations include taxes. This additional cost would not be included if a national economic or societal perspective was taken, however; in such an instance, other costs which impact on society, like environmental costs, would need to be reflected. For the present, no adjustment has been made for these items.

3.4 Life-cycle cost estimates of energy services

The LCC estimates for cooking, water- and space-heating, lighting and refrigeration which follow are provided for a national average and then disaggregated to show the differences between Johannesburg, Durban, Port Elizabeth and Cape Town. The estimates of cost are expressed as follows:

- for thermal energy services: Rands per unit of useful energy;
- for lighting: Rands per 1000 lumenhours;
- for refrigeration: Rands per litre (normalised for a 200 litre fridge/freezer).

Detailed calculations are included in Appendices B to F. The LCCs are arranged in ascending order to facilitate easy identification of financial cost rankings. For purposes of this ranking, the Johannesburg LCCs are used as the sorting costs.

3.4.1 Cooking

The range of appliances considered are those using electricity, paraffin, LPG, wood, and coal. The prices of these fuels vary from city to city, and in some instances so do the prices of appliances (good examples are coal stoves). However, appliance prices are maintained constant for each urban area.

The classes of cooking appliances considered include:

- top cookers: electric hot plates;
- gas and paraffin cookers;
- solid fuel stoves;
- electric and gas ovens; and
- microwave ovens.

Within each of these classes of cooking appliances there are sub-classes. Sub-class distinctions are necessary to define so as to be able to provide justifiable comparisons. For example, the energy performance of a large oven will be different from that of a small oven because of the heated surface area-to-volume ratio. (In general, South Africa ovens appear to be oversized for daily services.) Likewise, pressurised paraffin cookers primus will display a different

performance pattern when compared with a wick cooker. For the sake of simplicity, many of the sub-classes are aggregated into the broader categories mentioned above. The quality of service is assumed to be equivalent across the appliance range.

The prices of appliances utilised in the LCC estimates are listed in the table below. This data was collected in Cape Town using the questionnaire in Appendix G which captured the raw data appended in Appendix H.

<i>Class of cookers</i>	<i>Lowest price (excl. vat)</i>		<i>Highest price (excl. vat)</i>	
Top cookers: electric hot plates	109	Pineware 1021	395.9	Philips
Gas cookers	25	cooker top and No.3 bottle	55	cooker top and No. 13 bottle
Paraffin cookers (wick)	23	Flame single	221	Beatrice
Paraffin cookers (pressure)	64	local primus	221	imported Primus
Solid fuel stoves (cast iron)	1 516	Falkirk Dover No. 6	3 071	Falkirk Dover No. 88 smokeless
Brazier and 3-stone fire	0		0	
Electric ovens	1 399	Estia	3 921	Defy 131
Gas ovens	690	*	3 675	*
Microwave ovens	639	Daiwoo 60s	3 821	Sharp R851

TABLE 3.4 Cooking appliances and their prices

Sources: Various appliance retailers and wholesalers (see Appendices B to E)

The LCC estimates are best described graphically. The national average LCCs for cooking are included in Figure 3.2 below.

FIGURE 3.2 National average LCC estimates for cooking

Figure 3.2 shows the life-cycle estimates for cooking for the middle of all ranges for an aggregate value of all four urban areas. Figure 3.3 shows the regional variations in LCC for the different metropolitan areas. The ranking is from lowest to highest cost for Johannesburg.

FIGURE 3.3 Life-cycle cost estimates of cooking

Predictably the lowest LCCs are those for coal-burning appliances. The coal based cooking LCCs are followed by the electrical hot-plates and gas rings. It is apparent that gas is expensive in Johannesburg, where the LCC is considerably higher than Durban and Cape Town. In these cities gas rings are cheaper to use than in Port Elizabeth and Johannesburg where electric hot-plates would appear to be a better option.

The LCCs of the electric and gas stoves and ovens are jeopardised by comparatively high first-costs. The high LCC of the micro-wave could be attributed to the low utilisation time per annum in relation to a high capital cost.

The LCC regional variations are most apparent in the case of coal (between Johannesburg and Durban) and shows the lowest variation in the case of electrical appliances.

3.4.2 Space-heating

There are a variety of classes of space-heaters considered in this section:

- electric, gas and paraffin radiant heaters;
- electric fan and convection (finned) heaters
- electric heat-pumps;
- solid fuel appliances without chimneys; and
- solid fuel appliances with chimneys.

Not considered are passive design features which could mitigate heating requirements or replace them entirely in some of South Africa's climatic zones.

Space-heating is a complex issue as it is a service often incidentally derived from other energy services, such as cooking or water-heating. In fact, a large proportion of the thermal energy involved in providing these services will end up as space heat. Sometimes this is a benefit, while at other times it is not - for example, during hot periods of the year. The range of contribution to space-heating of, for example solid fuel stoves, is estimated in the life-cycle estimates. The life-cycle estimates illustrated below consider only the benefits of space-heating during a 4-6 month (2-4 month in the case of Durban) annual heating season. The multi-utility feature of cooking appliances is most notable for appliances such as coal stoves, which in winter are also heavily relied on as space-heaters.

In South Africa, electric space-heating appears to be of increasing concern for the electricity supply industry, which experiences annual peak demands coinciding with the coldest evenings of the year. This trend will undoubtedly be exacerbated as access to electricity increases.

The LCC estimates for the different classes of space-heating appliance/fuel combinations in the various urban areas are illustrated below. Detailed spreadsheets of the data behind these calculations are presented in Appendices B to F. Table 3.5 is a list of common space-heaters and their prices.

<i>Class of space heaters</i>	<i>Lowest price (excl. vat)</i>		<i>Highest price (excl. vat)</i>	
<i>Electric</i>				
Radiant heaters	40	Nu world 800 watts	278	De Longhi
Oil-filled heaters	229	Saisho 9 fin	836	MCE 11 fin
Fan/blower heaters	149	De Longhi	219	De Longhi
Gas heaters	124	Safire	647	Bosch Rollabout
Paraffin heaters	20	Rondowick	50	Rondowick
Electric heat-pumps	6 000	*	8 000	*
Solid fuel appliances without chimneys (brazier)	0	self-made	0	self-made
Solid fuel appliances with chimneys	714	Falkirk Queen Anne	3 502	Falkirk Dover No. 88 smokeless

TABLE 3.5 Space heaters and their prices

Figure 3.4 illustrates the national average LCC for space-heating.

FIGURE 3.4 National average LCC estimates for space-heating

Figure 3.5 shows the fuels and appliances used for domestic space heating in the four urban areas.

FIGURE 3.5 The life-cycle cost estimates of space heating

The lowest financial cost incurred by users to meet their space heating needs is associated with the use of electric heat pumps, coal and wood. The lowest cost is the heat pump followed by the coal brazier which, though cheap, is extremely smoky. Both coal and wood burned in this manner would emit almost all their heat to space-heating, but the crude 'appliance' does not have a chimney. In the present LCC analysis these negative externalities are not reflected, but their consideration could, in principle, lead to a different ranking of options.

After the solid fuels, the electric heat pump provides a good option, but heat pump applications are currently limited to locations where large space-heating loads are desirable. Applications of this technology, which is very costly in first-cost terms, would be limited to multi-family dwellings (such as hostels) or commercial buildings.

Paraffin heaters appear to be a good option before the other electric heaters, and gas is the most costly. In almost all cases, the LCCs in Durban are higher than elsewhere because of the shorter heating season.

3.4.3 Water-heating

Water heating is the last of the thermal energy services to be considered. This service can be provided using the following classes of water-heating systems:

- electric hot-water storage geysers;
- solar/electric hot-water storage geysers;
- solar-only hot water geysers;
- electric and gas in-line instantaneous water heaters;
- water heating using solid fuel stoves with a hot water jacket; and
- water heating in a pot on an electric, paraffin, coal, wood, or gas cooker.

<i>Class of water heaters</i>	<i>Lowest price (excl. vat) (* includes installation costs)</i>		<i>Highest price (excl. vat) (* includes installation costs)</i>	
Electric hot water storage heaters	1 117	Kwikot ("sinkhot") 100l, 100 kPa	2 309	Kwikot 200l 100 kPa
Gas hot water storage geyser	4 800	Valiant 190l (8.2 kW)	5 000	Valiant 220l (8.6 kW)
Solar/electric hot water geysers	4 676*	Sol Energy 200l 200 kPa	6 195*	Mikado 200l (3 kW)
Solar only hot water heaters	482*	Sol Energy 100l	1 234*	Sol Energy 100l
Electric in-line water heaters	820.8	AEG MT 60 5.75 kW 3.1 l/min	1 098	AEG DD LT 18/21 kW, 10.5 l/min
Gas in-line water heaters	1 117	Junker 5l/min	2 849	Valiant 275 10 l/min
Solid fuel heater with water jacket and high pressure boiler	1 835	Falkirk Union No. 9	3 406	Falkirk Dover 88
Heating in pot on electric, coal etc.	see cooking above			

TABLE 3.6 Water heaters and their prices

Figure 3.6 illustrates the national average LCCs for water heating options.

**FIGURE 3.6 National average LCC of water heaters**

The LCC estimates for the different classes of water-heating appliance/fuel combinations in the various urban areas are illustrated below in Figure 3.7. Detailed calculations behind this figure are in Appendices B to F.

FIGURE 3.7 The life-cycle cost estimates of water heating

The lowest cost option for water-heating is the integral solar water heater. However, it is perhaps unfair to compare this class of heater with other water-heating systems because hot water will not always be available on demand. This is similarly the case for the second-lowest option, the water jacket (with high pressure boiler) on the coal stove, which is in a similar class to the integral solar water heater in that a fire would have to be ignited prior to the water being heated and this may take some time - in other words a coal stove also does not provide hot water on demand.

Next is the solar/electric water-heater which tops up the solar energy shortfall with electricity, combining the best of cheap solar energy and hot water on demand. Solar electric water-heaters have high first-costs which would constitute a considerable barrier for low-income households, unless the purchase is arranged through a housing bond or some other facility at the time of purchase.

The hot-water storage geysers using gas and electricity respectively follow the electric in-line heaters, which, while not expensive in first-cost terms, have high power demands which are, for the larger flow systems, only available where three-phase electricity connections are in place. Three-phase is a technology option being decreasingly utilised in newly electrified households. Low-income households are more and more frequently being connected to 20 Amp single-phase supplies, which facilitate only very low-flow in-line heating - typically less than 5 litres per minute.

After the gas in-line heaters, paraffin options on conventional multi-purpose primus and wick stoves are the next lowest cost options.

3.4.4 Lighting

The classes of lighting considered are:

- electric incandescent;
- electric fluorescent;
- candles;
- paraffin wick;
- paraffin pressure; and
- gas lamps.

<i>Class of lighting</i>	<i>Lowest price (excl. vat)</i>		<i>Highest price (excl. vat)</i>	
<i>Electric incandescent</i>				
60 watt	2.10	•	2.70	Philips
100 watt	2.17	•	3.00	Mercury
<i>Electric fluorescent</i>				
10-11 watt	53	Mercury	68.39	Sanji
13 watt	53.98	Philips	54.99	Mercury
18 watt	56.99	Philips ES	68.39	Sanji
Candles	0.35		0.65	
Paraffin wick	8	Hazel lamp	14	•
Paraffin pressure	199	Coleman	239	Coleman
Gas lamps	64	Cadac 100 cp	105	Cadac 300 cp

TABLE 3.7 Light sources and their prices

The LCC estimates for the different classes of lamp/fuel combinations in the various urban areas are illustrated below in Figures 3.8 and 3.9. A detailed spreadsheet of the data behind these figures is presented in Appendixes B to F.

FIGURE 3.8 The life-cycle cost estimates of lighting

The results reflected in Figure 3.8 are clear-cut. The electric options are considerably lower-cost options than the others per unit of light output. Paraffin and gas pressure lamps follow with comparable costs. Candles are the most expensive after paraffin hurricane lamps. It is questionable, however, whether the methodology for evaluating the cost of light should not be costs per light source, regardless of the *quality* of lighting service provided. Cowan et al (1992) estimate these costs, which reflect a close correlation between electric lighting and candles as *light sources*.

FIGURE 3.9 The life-cycle cost estimates of some electrical lighting options

Figure 3.9 shows the costs of the least-cost electric lighting options. The compact fluorescents (CFLs) of higher efficacy, cost in life-cycle terms about one-eighth of the incandescent options with similar light outputs. Unfortunately CFLs have a low penetration, once again as a result of their initial purchase prices, which are often 20 times those of the incandescents. The penetration of CFLs is likely to remain low unless this barrier is addressed.

The variation between the life cycle-costs from city to city are low enough to make an national average comparison unnecessary.

3.4.5 Refrigeration

The classes of refrigerators costed include:

- electric 250 to 300 litre fridge/freezers;
- electric 330 litre upright freezers;
- electric 120 to 300 litre chests freezers; and
- gas or paraffin absorption fridges/freezers.

Class of fridge/freezer	Lowest price (excl. vat)		Highest price (excl. vat)	
Electric 250 to 330 litre fridge/freezers	1 599	Fridgemaster 255	3 820	KIC 265
Electric upright freezers	2 339	Kelvinator FA 330	3 838	Kelvinator FA 330
Electric 120 to 300 litre chests freezers	999	KIC 210 and Defy 210	2 718	Defy 420
Gas absorption fridge/freezers	1 400	KIC 110	3 675	KIC 220

TABLE 3.8 Refrigerators/freezers and their prices

As there are very little data on the efficiency of refrigerators sold on the South African market, the range of efficiencies of refrigerators of comparable size and class is used as an approximation. This approximation is partly flawed in that the countries in which the energy efficiency of appliances are available are most likely to be countries with either (or both) appliance labelling schemes and/or minimum energy performance standards. In 16 countries comparative or endorsement labels do exist (Duffy 1996), but even then the testing procedures may have little correlation with the real performance of the appliance in use. Refrigerators demonstrate the fallibility of transforming test data to in situ data as performance is sensitive to ambient temperatures. For example, the European Union refrigerator standard ISO 5155 - 1983,

conducts tests at 25°C and Australian standards at 32°C. The European test requires a fully loaded fridge while the Australian test method requires standard packing of the fridge.

Currently Eskom is testing a range of the most popular fridges sold in South Africa to obtain a performance baseline for an energy performance labelling feasibility study (Smoog 1996). Initial estimates of efficiencies of South African refrigerators and freezers utilised in the estimates was sourced from Power People Manufacturers (1996). This data is not documented, but it is the only available data on the energy performance of refrigerators available in South Africa at the time of writing.

A possible way of estimating the energy consumption of South African refrigerators is to multiply the rated power consumption of the compressors by a factor of between 0.5 and 0.8. Fridgemaster, which enjoys the largest portion (nearly 40%) of the South African refrigerator market, uses a 50% to 80% running time rule-of-thumb in matching fridges and compressors (Shear 1996). Power People Manufacturers (1996) indicate that from their energy performance tests of refrigerators, energy consumption differences between the most and least efficient fridge in South Africa is in the region of a factor of 10 for similar classes and volumes!

Figure 3.10 illustrates the national average LCC of domestic refrigeration equipment.

FIGURE 3.10 National average LCCs for refrigeration equipment

The LCC estimates for the different classes of refrigerator/fuel combinations in the various urban areas are illustrated below in Figure 3.11. A detailed spreadsheet of the data behind these calculations is presented in Appendixes B to F.

FIGURE 3.11 The life-cycle cost estimates of refrigerators

It is apparent from the figure that electric fridges and freezers and fridge/freezers have LCCs less than half those of the gas and paraffin absorption refrigerators. As with lighting, electrical options are far less expensive for users over the life of the appliance. Chest freezers, that usually have 10 cm of insulation material and are top-opening, have the best performance.

3.5 Conclusions

Chapter 3 has presented the financial life cycle costs of various appliance-fuel combinations, using many assumptions pertaining to key variables.

There are some conclusions from the LCC analysis:

- A wide range of life-cycle costs can be expected for any single appliance fuel combination.
- In the majority of the cases, the present value of operational costs are larger than the present value of initial costs. Exceptions to this include (most notably) microwave cooking, in which appliance costs dominate.
- For cooking, coal has the lowest LCC in Johannesburg and Port Elizabeth, followed by electric hot-plates and gas burned on a ring. In Durban and Cape Town, the gas price is low enough to make cooking with gas a better option than with electricity.
- In water-heating, solar water-heaters provide the lowest financial cost options. Electric hot water storage geysers have comparatively high LCCs.
- For space-heating, electric heat-pumps, followed by coal used in a brazier or a stove, have the lowest LCCs.
- For lighting and refrigeration, grid connected electrical options have lower LCCs than the other options.

4

Sensitivity analysis

4.1 Sensitivities of life-cycle costs

The LCC estimate is subject to a number of assumptions and parameters that can have a range of values. This chapter sets out to assess how sensitive the LCC estimate is to some of these assumptions and parameters. In undertaking the sensitivity analysis, the LCC is estimated by changing one variable across a range while all other variables and assumptions remain constant. The variables and parameters against which the LCCs are tested in this sensitivity exercise are:

- the price of the fuel;
- the price of the appliance;
- the appliance efficiency;
- the rate of consumption of fuels;
- the durability of the appliance; and
- the discount rate.

For the first three variables listed above, a range is defined in the LCC calculations. The mid-point of this range was used for demonstrating the average LCC (described in Chapter 3), but for the sensitivity analysis five equidistant increments are set between the maxima and minima, at which the sensitivity is tested. This method thus provides six points at which sensitivity is tested. The result of the test is presented as the percentage change in LCCs using the LCCs at the bottom of the range as a baseline. A second presentation of sensitivity shows the effect on the LCC of five appliance combinations – coal stove, paraffin wick and primus, gas ring and electric hot-plate for cooking at minimum, mid and maximum points on the variable's range. In the case of the last three variables, an estimate of the reasonable fluctuation in the parameter is also divided into four increments. For example, 8, 12, 16, 20, and 24% increments for the discount rate analysis, and 5, 15 and 25% above and below the mid-point are used for assessing the sensitivity to variable durability.

Rather than conduct sensitivity analysis on all the estimates for all the urban areas, the national average LCCs for cooking serve as the test case. Figure 4.1 describes the connection cost, maintenance cost, operation cost and appliance price contributions to the LCC for cooking appliances. It is evident that the operational costs and appliance prices dominate the LCC, and that the ratio in the majority of cases is weighted towards a larger contribution from the operational costs.

FIGURE 4.1 Contributions to the life-cycle cost

Table 4.1 summarises the variables and the ranges and increments at which the life-cycle costs were tested.

Variable	Top of the range	Bottom of the range	Increments
Price of the fuel	home light 1 (in most cases)	municipal tariff	20%
Price of the appliance	highest price	lowest price	20%
Efficiency	most efficient	least efficient	20%
Durability	25% above listed estimate	25% below listed estimate	10%
Discount rate	24%	8%	4%

TABLE 4.1 Sensitivity variables, ranges and increments

4.1.1 Sensitivity of life-cycle cost estimates with respect to variable fuel prices

The sensitivity of the LCC is tested with respect to increasing fuel prices. The result of the exercise is illustrated in Figure 4.2.

FIGURE 4.2 Life-cycle cost sensitivity to fuel price variations

The increase in the price of fuel results in increasing LCCs for all fuel/appliance combinations. In the case of the gas ring, the sensitivity analysis revealed pronounced increases of up more than 50% as the fuel price was increased across the range of fuel prices. The high sensitivity of gas could be attributed to the broad fuel price range of between 1.66 and 3.66 Rands per kilogram. In addition, when referring to Figure 4.1, the gas ring shows that more than 90% of the LCC is made up of the operation cost component, which further exacerbates the sensitivity to fuel price. For the other appliances the range is far more modest, with the least variation being displayed by the electrical appliances, of which the oven and micro-wave oven display the lowest operation components in the LCC. Electricity prices are confined to a relatively narrow price range which further desensitises life-cycle cost to fuel price variations.

FIGURE 4.3 Effects on LCC of varied fuel prices

Figure 4.3 is derived from Figure 4.2 by converting the % increases into Rands per 10 Megajoules reflecting the LCC at the lowest, mid and highest prices in the fuel price range. It also visually reveals the high sensitivity of the LCCs of gas- and paraffin-based cooking to fuel price increases, while electrical and coal based cooking show little sensitivity.

4.1.2 Sensitivity of life-cycle cost estimates with respect to variable appliance prices

The sensitivity of the LCC is tested with respect to increasing appliance prices. The result of the exercise is illustrated in Figure 4.4.

FIGURE 4.4 Life-cycle cost sensitivity to appliance price variations

As was seen in the case of fuels, an increase in the price of appliances results in an increase in LCCs, the most pronounced increases appearing where the range of prices of the appliances is the largest. This is the case with both paraffin appliances which, though modestly priced, have a wide price range between local and imported goods. Low sensitivity to appliance prices are revealed in the cases of the coal and gas burning appliances. Figure 4.5 shows the actual LCC variations across the range for cooking appliances.

FIGURE 4.5 Effects on LCC of varied appliance prices

Figure 4.5 shows the higher sensitivity of paraffin cooking appliances and the lower sensitivity of coal- and gas-based cooking to variations in the price of appliances. Coal stoves have the lowest LCC across the appliance price range.

4.1.3 Sensitivity of life-cycle cost estimates with respect to variable efficiency

The sensitivity of the LCC is tested with respect to increasing appliance efficiency. The result of the exercise is illustrated in Figure 4.6.

FIGURE 4.6 Life-cycle cost sensitivity to appliance efficiency variations

The increase in appliance efficiency reduces, as expected, the LCCs of fuel and appliance combinations. Across the efficiency range, LCCs vary for the selection of appliances between 15 and 45%, the highest being where the efficiency range is at its broadest, as is the case for the solid and liquid fuelled appliances. A general conclusion which can be drawn is that there is a wide range of estimates, which will obviously affect the calculation of LCCs. Where the costs of fuels are a relatively smaller part of the LCC, and the efficiency range lowest (as is the case with the micro-wave oven), the LCC estimate is least sensitive to variations in efficiency. Most sensitive are the paraffin appliances, followed by coal burned in a brazier. Figure 4.7 shows the actual changes in LCC for cooking with increasing efficiency.

FIGURE 4.7 Effects on LCC of increasing efficiency

The most heavily affected by the increase in efficiency are the paraffin appliances which show a rapid reduction in the LCC across the range. Reductions in the LCCs of electrical, gas and coal based cooking show less dramatic reductions.

4.1.4 Sensitivity of life-cycle cost estimates with respect to variable power assumptions

The sensitivity of the LCC is tested with respect to changes in the average power output (or the number of units of fuel utilised in an hour of operation). This 'power factor' estimate can vary considerably between settings for any appliance of variable operation – for example, a stove could have between one and four plates in use at any one time. Nevertheless, as the basis of the LCCs is in useful energy units (10 MJ), there is no sensitivity to the LCC estimate with changing power assumptions.

4.1.5 Sensitivity of life-cycle cost estimates with respect to durability assumptions

The sensitivity of the LCCs were estimated with respect to a factor that describes the number of useful years of operation which could be expected from the appliance. Figure 4.8 shows the effects on LCC when the useful durabilities of the appliances are changed.

FIGURE 4.8 Life-cycle cost sensitivity to durability variations

The LCCs decrease in all cases (although where the appliance costs nothing, as is the case with the coal brazier, there is obviously no change). The appliances which are the most affected are the paraffin primus and the electric oven, which have relatively high first-cost to operating-cost

ratios. The sensitivity to durability of appliances appears modest when compared to other variables tested in this analysis. Figure 4.9 shows the effect on LCC of increasing durability.

FIGURE 4.9 Effects on LCC of increasing appliance durability

The figure reiterates the modest changes in LCC with increasing appliance durability. Only the paraffin combinations show pronounced changes across the range.

4.1.6 Sensitivity of life-cycle cost estimates with respect to variable discount rates

The sensitivity of the LCC is tested with respect to fluctuations in the discount rate. In conducting the exercise, the discount rate used to calculate the Net Present Value (NPV) of the all the costs was altered from 8-24%, while the discount rate used in the amortisation of the NPV was kept constant at 10%. The result of the exercise is illustrated in Figure 4.10.

FIGURE 4.10 Life-cycle cost sensitivity to real discount rates

The relationship between LCC and real discount rates is non-linear, as expected. It was expected that in all cases an increase in the discount rates would result in a decrease in the LCC. This trend is reflected in the present value of the LCCs, and the amortised the LCCs per unit of energy.

The largest increases are recorded for the coal stove, gas-ring, and electric hot plate. The smallest changes in LCCs are recorded for the paraffin appliances and the coal brazier. Figure 4.11 shows the sensitivity of the LCC to discount rate increases.

FIGURE 4.11 Effects on the LCC of an increasing discount rate

Figure 4.11 shows the modest sensitivity of all the fuel and appliance combinations to increases in the discount rate.

4.2 Conclusions

Chapter 4 has presented the sensitivity to some key assumptions and variables, of the national average amortised LCCs for cooking services. There are a few conclusions which can be drawn from this analysis:

- The LCC of gas cooking is highly sensitive to fuel price increases whereas electrical cooking shows a low sensitivity.
- The LCCs of cooking using an electric stove, microwave or a paraffin primus are most sensitive to appliance price increases.
- All appliance/fuel combinations are affected by increases in efficiency. Most sensitive are the paraffin appliances and least sensitive are the electrical stoves and ovens.
- The LCCs of all combinations are not affected greatly by changes in the durability of the appliances and efficiency.
- The LCCs were in general most sensitive to fuel and appliance price changes across the range.
- Throughout the sensitivity study, coal-based cooking in a stove remained on average the least-cost option for cooking in South African cities, with gas and electric heating appearing similar in LCCs.

5 Conclusions

It is clear that the ranges of LCCs are broad, in some instances extending to three times or more the minimum of the range. In most cases an estimated range of LCCs does not provide incisive clarity to the end-user who wants to know which appliance/fuel combination will deliver the lowest-priced energy service to the end-user. This reflects the reality of appliance and fuel combinations in use. Because the cost depends on a large number of parameters, not least the behaviour of the user, there is much uncertainty as to which combination will provide the least-cost service, so the compounding effect of many small variations in the parameters can result in large LCC variations.

The conclusion that too much variation exists to make direct comparisons is not, thankfully, the rule. Some appliance fuel combinations provide services distinctly cheaper than the rest. Lighting and refrigeration are services where grid electricity will provide considerably lower cost services than all other competitive commercial fuel and appliance combinations. Similarly, a clear conclusion can be drawn from the range of LCCs describing water-heaters, where integral solar water heaters have significantly lower LCCs than all others. But despite the low LCC at which the integral solar water-heater provides the service, the quality of the service cannot be realistically compared with the provision of hot water on demand. A second best could be either a solid fuel stove with a water jacket or a solar/electric water heater, which uses electricity to top up the solar shortfall and provide hot water on demand.

The comparisons of levels of service with respect to water-heating is one methodological question that needs to be considered when policy is developed, but a similar question can be raised about the LCC methodology when applied to lighting. Will, for example, users be making choices on the basis of lumens when choosing lighting, or will any light source be adequate for their needs, regardless of its quality? If the latter is closer to the users' reality, then a candle may provide a lower cost lighting source than the electric lamp. Such observations may provide some insight into the slower than expected movement towards electrical saturation of low-income household energy services, and questionable bases for analysis and marketing.

Amongst the thermal energy services, uncertainty about the lowest-priced option is greater as LCCs are confined within a comparatively narrow range compared to, say, the lighting LCCs. It is apparent that unless solid fuels are available, cheap and clean, the possibility to meet energy service needs could feasibly be any one of the electrical, gas or paraffin options, although what has not been factored in are the externalities that can affect health negatively through burns, indoor and outdoor air pollution and fires.

The main conclusions which can be drawn from the life-cycle cost analysis are the following. The least financial cost options for fulfilling the energy services are:

- coal stoves for cooking;
- heat-pumps (for multi-family dwellings and commercial buildings) and by coal stoves for space heating;
- integral solar water heaters for water heating;
- 18W compact fluorescents for lighting; and
- electric fridges and freezers for refrigeration.

The outcome of this life-cycle costing exercise should ideally be used to develop a least-cost mix of options from a national economic perspective. However, this is the content of the following paper in this series.

The sensitivity of the average national LCCs for cooking fuels and appliances were tested by varying fuel price, appliance price, energy efficiency, durability and real discount rates independently. As fuel price and appliance prices increase, so do the LCCs. When energy efficiency, discount rate and durability increase, the trend is one of decreasing LCCs. The sensitivity is linked to the proportional contributions to the total LCC of the operational and appliance price components and the breadth of the ranges being tested. For example, gas rings

for cooking have a LCC which is almost entirely made up of operational costs. So there is lower sensitivity to, appliance durability and the discount rate, and energy efficiency variations than to fuel and appliance prices.

A general observation with respect to the sensitivity analysis, was that there was a strong linear sensitivity to fuel and appliance price variations. The sensitivity to the remaining variables (efficiency, discount rate and durability) were linear and less strong within the ranges tested.

Appendix A

1. The life-cycle cost estimate

The life-cycle cost provides an estimate of the cost in current financial terms of all the costs involved in the use of an appliance, from purchase to the disposal. The life-cycle cost (LCC) is composed of the sum of the initial costs, the present value of any replacements or maintenance, and the present value of operational costs. The life-cycle cost is the present value cost of the entire system over the appliance's lifetime (Davis 1991). In the calculations below the LCC is presented in 1996 Rands per 10 Megajoules of useful energy. The useful energy is the delivered energy multiplied by the efficiency of energy transformation of the appliance.

The LCC includes the actual amount paid for the asset (appliance), C , the present value of replacing all or part of that asset R_{pva} , the present value of replacing the connection to the energy infrastructure (electrical or gas) R_{pvc} , the present value of operating the appliance O_{pv} , and the present value of the maintenance M_{pv} , that would be required by the appliance over the life-cycle.

$$LCC = C + R_{pva} + R_{pvc} + O_{pv} + M_{pv} \quad (1)$$

1.1.1 The cost of the appliance (C) and its replacement cost (R_{pva})

The cost of the appliance can be obtained from retailers and manufacturers. The replacement cost of the appliance is calculated using the following equation:

$$R_{pva} = C * ((1 + esc_p) / (1 + dr))^n \quad (2)$$

n is the life of appliance in years. The terms esc_p and dr refer to the escalation in the cost of the purchase price of appliances and the discount rate gives an indication of the future value of money.

The replacement cost of the appliance is estimated using the operational lifetime and dividing this by the time the appliance is in use during an average year. In the life-cycle cost estimates in this paper, the operational or useful life of the project coincides with the life-cycle of the project, therefore there is assumed to be no residual value accorded the appliance. Similarly, replacement of parts of the appliance is covered in the maintenance cost estimate.

For the minimum replacement costs, the minimum cost of the appliance is used and the maximum life in years is used. For the maximum replacement costs, the maximum cost of the appliance and the minimum life in years is used.

1.1.2 The operating costs of the appliance (O_{pv})

This quantity is calculated from the annual operating costs over the life of the appliance. The annual operating costs is the product of the annual operational hours, the average power estimate (fuel use per unit of operational time) and the cost of the fuel.

$$O_{\text{annual}} = \text{hours used per year} * \text{units per hour} * \text{cost per unit} \quad (3)$$

The present value of operation is:

$$O_{pv} = O_{\text{annual}} * ((1 + esc_o) / (dr - esc_o)) * (1 - ((1 + esc_o) / (1 + dr))^n) \quad (4)$$

The terms esc_o and dr refer to the escalation in the cost of operating the appliance (fuel price increases) and the discount rate gives an indication of the future value of money.

The minimum operating cost is calculated using the lowest annual operational time and the lowest price for the fuel. The highest operational costs are calculated using the highest number of hours per year and the highest fuel costs per unit.

1.1.3 The maintenance cost of the appliance (M_{pm})

This quantity is calculated in a similar way to the operating costs. In most cases information on the maintenance costs of appliances is not readily available, and has to be estimated.

1.1.4 The amortised LCC per day

At this point the LCC can be calculated using equation 1, above. However, to amortise this down to a daily amount is the next step:

$$\text{LCC (amortised)} = \text{LCC} * ((1+dr)^n * dr) / ((1+dr)^n - 1) \quad (5)$$

The annualised LCC can be divided by 365 to provide a daily LCC¹.

1.1.5 The amortised LCC for ten Megajoules of utilised (useful) energy

The final step in the calculation is to give cost of providing a utilised arbitrary quantity of energy service. For most thermal energy services 10 Megajoules of utilised (or useful) energy is considered as the amount of heating energy for services of cooking, water heating and space heating, while for lighting 1 000 lumenhours is used. For refrigeration the volumes are normalised linearly to 200 litres and the life-cycle cost estimated in R/day.

$$\text{LCC (10MJ)} = 10 \text{ MJ} * \text{LCC (R per day)} / \text{MJ per day (utilised)} \quad (6)$$

The minimum LCC per ten Megajoules of useful energy is calculated using the minimum daily LCC divided by the minimum daily Megajoules and multiplying this by ten. The maximum LCC per ten Megajoules of useful energy is calculated using the maximum daily LCC divided by the maximum daily Megajoules, dividing by the conversion efficiency and multiplying this by ten.

¹ The daily amortised figures can be calculated using the Microsoft Excel function $\text{PMT}(\text{LCC}, dr, n)/365$.

Appendix G: Appliance price questionnaire

From: Steve Thorne
Energy for Development Research Centre
Private Bag Rondebosch
7700 Rondebosch
Phone: 650 3230
Fax: 650 2830

Retailer name:			
Person referred to:		Phone no:	

1.1 List the 3 fastest moving refrigerators, name the model (volume), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

1.2 List the 3 fastest moving refrigerator/freezers (volumes), name the model, estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

1.3 List the 3 fastest moving freezers, name the model (volume), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

2.1 List the 3 fastest moving stoves, name the model (features), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

2.2 List the 3 fastest moving hobs/top-cookers, name the model (features), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

2.3 List the 3 fastest moving micro-waves/ other cookers, name the model (features), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

3.1 List the 3 fastest moving heaters, name the model (features), estimate turnover in an average month, list the price, estimate proportion on HP.

model (volume)	numbers/ month	price		% on HP

4.1 List the 3 fastest moving water heaters, name the model (volume, kW), estimate turnover in an average month, list the price, estimate proportion on HP.

model (features)	numbers/ month	price		% on HP

5.1 List the 3 fastest moving lights, name the model (volume, watts), estimate turnover in an average month, list the price, estimate proportion on HP.

model (features)	numbers/ month	price		% on HP

6.1 List the 3 fastest moving fluorescent, name the model (volume, watts), estimate turnover in an average month, list the price, estimate proportion on HP.

model (features)	numbers/ month	price		% on HP

7. others

model (feature)	numbers/ month	price		% hire purchase

8. Please describe the financing schemes, and terms.

income level	references	%	duration

9. Who do you sell to?.....

10. What's your edge?.....

11. Would appliance energy labelling assist in the your work?.....

	price numbers	14.99	10.6	10.48		
	model	Mercury	Thorn			
	volume	6*60w	5*100w	5*100		
	price numbers	12.99	11.59	10.48		
	model	Mercury	Thorn			
	volume	6*100w	5*60w			
	price numbers	12.99	11.19			
CFLs	model	Mercury	Philips ES	Philips SL		
	volume	10w	13w	18w		
	price numbers	52.99	53.98	58.45		
	model	Mercury	Philips ES	Sanji		
	volume	13w	18w	11w		
	price numbers	54.99	56.99	68.39		
		Mercury		Sanji		
		18w		18w		
		62.99		68.39		
Paraffin	model	Hazel Lam Coleman (pressure lamp)				
	volume					
2 wicks = 3.49	price				7.99	199 to 239
wick holder = 5.1	numbers					
Gas	model					Cadac
	volume					100 CP
	price numbers					64 36
	model					Cadac
	volume					300 CP
	price numbers					105 18
